# Photogrammetric Work Without Blunders 

Kurt Kubik and Kenneth Lyons<br>Department of Surveying, University of Queensland, St. Lucia, QLD, Australia 4067<br>Dean Merchant<br>Department of Geodetic Science and Surveying, The Ohio State University, 1958 Neil Avenue, Columbus, OH 43210-1247

#### Abstract

The method of least squares is unsuitable for dealing with blunders in measurements. Other so called robust computation methods are explained and applied to photogrammetric problems (relative and absolute orientation) enabling the automatic detection and elimination of blunders. It is shown that these robust methods considerably improve the photogrammetric mapping process.

## REVIEW OF ROBUST ESTIMATION METHODS

Alternative methods to least-squares adjustment have been proposed in recent years (see, for example, Fredriksen et al. (1985) and Kubik et al. (1986)) which reduce the influence of blunders in the computation process. These are the so called robust estimation methods. Robust estimators are estimators which are relatively insensitive to limited variations in the frequency distribution function of the measurements and, thus, to the presence of outlyers and blunders. All these methods have in common: they do not minimize the (weighted) square sum of residuals, i.e.,

$$
\begin{equation*}
\sum_{i=1}^{n} r_{i}^{2} \rightarrow \min ; r_{i} \text { residuals } \tag{1}
\end{equation*}
$$

but, rather, a properly chosen function $\Phi$ of $r_{i}$ which, for large values of $r_{i}$, increases less rapidly than $r_{i}{ }^{2}$, i.e.,

$$
\begin{equation*}
\sum_{i=1}^{n} \Phi\left(r_{i}\right) \rightarrow \min . \tag{2}
\end{equation*}
$$

Examples for the choice of $\phi$ are

$$
\begin{aligned}
& \Phi\left(r_{i}\right)=\left|r_{i}\right| \text { and } \\
& \Phi\left(r_{i}\right)=r_{i}^{2} \exp \left(-r_{i}^{2} / a^{2}\right)
\end{aligned}
$$

The numerical solution of Equation 2 can be obtained by using the method of "reweighted least squares." Equation 2 can be written as

$$
\Sigma p\left(r_{i}\right) \times r_{i}^{2} \rightarrow \min
$$

where the weight function $p\left(r_{i}\right)$ is given by

$$
\begin{equation*}
p\left(r_{i}\right)=\frac{\Phi\left(r_{i}\right)}{r_{i}^{2}} \tag{3}
\end{equation*}
$$

The procedure is iterative, starting with the least-squares solution $(p=1)$.

In the second iteration the individual weights are calculated from Equation 3 using the residuals from the least-squares solution. In the third and following iterations, the residuals from the previous iteration are used for calculating new weights. This procedure is continued until convergence is obtained.

## ROBUST ESTIMATION OF A MEAN VALUE

This section presents results from the application of three robust alternatives to the least-square method for estimating the mean value of a set of measurements. These examples serve to illustrate the flow of computation.

Let us assume the following sample of five values given: Z $=(10,11,11,12,100)$ and $\sigma=5$ units. The least-squares estimate for the mean is equal to $m=29$ units.

[^0]
## Least-Sum Estimation

In least-sum estimation, the weight function is chosen equal to $p_{i}=\frac{1}{\left|r_{i}\right|}$, thus minimizing $\left.\Sigma\left|r_{i}\right| \rightarrow \min .{ }^{*}\right)$. In Table 1, the iterative computation is shown. The second column of the table lists the weights $P_{\mathrm{i}}$ for the five measurements used for the weighted average computations. The last column lists the five residuals $\left|r_{i}\right|=$ abs $\left(\mathrm{Z}_{\mathrm{i}}-m\right)$ for every iteration.

The proper solution $m=11$ is obtained after ten iterations. This example illustrates the necessity to limit the absolute magnitude of $P_{i}$; otherwise, some measurements receive very large weights and the mean estimate becomes equal to these measurements.

## Hubers Estimate

In Hubers estimate (Kubik et al., 1986), the weight is limited in magnitude according to the following rule:

$$
\begin{aligned}
& P=1 \text { for }|r|<a \\
& P=\frac{a}{|r|} \text { for }|r| \geq a
\end{aligned}
$$

We use an iterative algorithm similar to the previous one and assume $a=2 . \sigma=10$ units. Table 2 summarizes the results.

The computation converges after three iterations to the mean estimate, 13.5. This estimate is different from before, as we are minimizing a different function Equation 2.

FIG. 1. Point Distribution for Relative Orientation, Photo No. 2

## The Danish Method

In the Danish Method, (Kubik et al., 1986) the weight of outlying measurements is reduced as the value of their residuals increases. The following weighting rule is used:

$$
\begin{aligned}
& P=1 \text { for }|r|<a \\
& P=\exp \left(-\frac{|r|^{2}}{a^{2}}\right) \text { for }|r| \geq a
\end{aligned}
$$

The results of the iterations are summarized in Table 3 (using $a=2 . \sigma)$.

Because the Danish Method uses exponential weights, measurements outside a chosen confidence interval are completely rejected, thus resulting in a truncated sample and mean estimator. Convergence of the iterations is extremely fast, and that is why we favor the exponential weight method over other methods.

## NUMERICAL RELATIVE ORIENTATION

Let us now consider the application of these robust methods to numerical relative orientation, based on the well known col-

linearity conditions. A simulated model with 17 points for relative orientation, as shown in Figure 1, is used for this purpose. At first, random errors of $\sigma=3 \mu \mathrm{~m}$ were superimposed on the ideal image coordinates and a least-squares adjustment was performed. The results are shown in Table 4, and the residual $y$ parallaxes are consistent with the initially introduced perturbance. Next, the least-squares relative orientation is repeated, but now a blunder of $40 \mu \mathrm{~m}$ is introduced in point 100. The results of the computations are shown in Table 5; the largest real parallax appears at point 103, thus making it a non-trivial task to properly locate the blunder, even with so many relative orientation points. The computation is repeated but now using robust estimation according to the least sum principle, and results are presented in Table 6. The blunder can now be clearly recognized in point 100 (as $2 \times 13.9 \mu \mathrm{~m} \sim 28 \mu \mathrm{~m}$ ).

Finally, the Danish Method is applied to this example. The results of Table 7 show that the total amount of the blunder is correctly found and eliminated. The magnitude of the estimated error is $2 \times 20.5 \mu \mathrm{~m}=41 \mu \mathrm{~m}$, corresponding to the $40 \mu \mathrm{~m}$ originally introduced, demonstrating the superiority of this method. The measurements at point 100 were iteratively weight reduced and finally, after 2 iterations, were assigned weight $\theta$.

## NUMERICAL ABSOLUTE ORIENTATION

As a final example, we illustrate the application of robust estimation to absolute orientation from an application in industrial photogrammetry. Consider five points to be given in the model and ground coordinate system as listed in Table 8 and shown in Figure 2. All magnitudes are transferred to mm at image scale.

In the $X$ and $Y$ coordinates of the last two points 9 and 11, blunders of $10 \mu \mathrm{~m}$ have been added to the model coordinates. Tables 9 and 10 summarize the results of absolute orientation according to the least-squares method and the Danish Method, respectively.

After least squares, the four blunders cannot be located in the residuals. There are large residuals at all points. The largest residual appears in point 1, and even advanced (Baarda) test theory does not allow a proper identification of the blunders. On the other hand, the Danish method clearly locates and eliminates the four blunders of $10 \mu \mathrm{~m}$, thus preserving the high accuracy of the other measurements of this example.

Table 7 Relative Orientation - Danish Method

| Point No. Photo No. |  | $X^{*}(\mathrm{~mm})$ | $\gamma^{*}(\mathrm{~mm})$ | $V X^{*}(\mu \mathrm{~m})$ | $V Y^{*}(\mu \mathrm{~m})$ | WT. |

| 5 | -0.009 | 0.008 | -0.003 |

## CONCLUSIONS

These few examples demonstrate how important it is in practical photogrammetry to use robust adjustment methods in simple operations like relative and absolute orientation, as well as in block adjustment. The reader should be aware that today many blunders go unnoticed, because the least-squares methods distribute them evenly over all measurements. Therefore, we strongly recommend that robust adjustment methods be used as a replacement for or error check of the conventional least-squares method. In particular, the Danish Method, developed by Krarup (personal communication) and further refined by the authors, proves to be a very effective tool for modern photogrammetric computations.

## CALL FOR PAPERS

# 32nd Annual International Symposium on Optical \& Optoelectronic Applied Science \& Engineering 

San Diego, California<br>14-19 August 1988

This symposium - sponsored by the Society of Photo-Optical Instrumentation Engineers (SPIE) - includes conferences designed to explore the latest developments in optical materials; photo-optical instrumentation engineering; optical and optomechanical technologies; infrared technology and cryogenic systems; information processing; $x$-ray instruments, multilayers, and sources; and the business side of optics for nontechnical personnel. Also presented in conjunction with this symposium will be a full program of tutorial short courses, engineering update courses, focused equipment demonstrations, and one of the industry's largest and most comprehensive technical instrument exhibits.
Specific conferences include Advanced Algorithms and Architectures for Signal Processing III; Advances in Optical Fabrication and Metrology; Airborne Reconnaissance XII; Applications of Digital Image Processing XI; Ceramics and Inorganic Crystals for Optics, Electro-Optics, and Nonlinear Conversion; Cryogenic Optical Systems and Instruments III; Current Developments in Optical Engineering III; Diamond Optics; High Brightness X-Ray Sources and Applications; High Speed Photography, Videography, and Photonics VI; Infrared Technology XIV; Large Optics Technology II; Linear and Nonlinear Optics with Single-Crystal Films; Nonlinear Optical Properties of Organic Materials; Optomechanical Design and Engineering to Facilitate Alignment; Properties and Characteristics of Optical Glass; Real Time Signal Processing XI; Statistical Optics; Stray Light and Contamination in Optical Systems; Thin Film Neutron Optical Devices: Mirrors, Supermirrors, Multilayer Monochromators, Polarizers, and Beam Guides; Underwater Imaging; X-Ray Instrumentation in Astronomy; and X-Ray Multilayers for Diffractometers, Monochromators, and Spectrometers. Those wishing to present a paper should indicate the particular conference in which they are interested, submit four copies of a brief professional biography, and submit four copies of a 200 to 300 word abstract typed double-spaced on $81 / 2$ by 11 white paper, by 15 February 1988 , to

Bellingham, WA 98227-0010
Tele. (206) 676-3290
